Bronze to Silver Mapping

Databricks Development Part 2 | Original question and answer

YOUR ORIGINAL QUESTION

I am studying the data generator code for now,

Quick Question: Can you tell me which entities that we have in bronze form the entity in Silver. I get there are 29 entities 26+ 3 events. BUt we wont create silver entity mapping 1to1 right? Multiple entities in bronze will form 1 entity in silver. if true understanding then give the list mapping you are thinking based on local data model of silver layer

MY ORIGINAL ANSWER

Your understanding is partially correct. In our approved Silver design, we will use both approaches:

1. 29 conformed Silver tables: Each logical source entity has a corresponding Silver table. Its Snapshot and CDC Bronze tables are reconciled into that one Silver table.

2. 6 additional Silver tables: These combine multiple conformed Silver entities or provide audit and processing controls.

Total: 35 principal Silver tables, as documented in Master Blueprint v2.0, Section 8.

1. Bronze → Conformed Silver (29 tables)

For example:

```
bronze.coverage_snapshot + bronze.coverage_cdc → silver.coverage
```

Domain	Bronze source entities	Silver tables
Membership & Eligibility	member_master, subscription, subscription_membership, coverage, enrollment	Same 5 names
Product & Group	product, benefit_plan, employer_group, employer_subgroup, plan_offering, plan_network	Same 6 names
Provider & Contracts	practitioner, practitioner_specialty, practitioner_role, supplier, supplier_location, network_participation, provider_contract, provider_contract_rate	Same 8 names
Address	address_master, entity_address	Same 2 names
Reference & Network	reference_codes, specialty, network	Same 3 names
Claims & Finance	claim_header, claim_line, claim_status_event, claim_adjustment, payment_remittance	Same 5 names

These tables will handle source validation, deduplication, CDC, MERGE, SCD and effective-dated business history.

2. Multiple Silver tables → Derived Silver (6 tables)

This is where we start combining entities and applying complex business logic.

Derived Silver table	Main contributing Silver tables
member_eligibility	coverage + enrollment + subscription + subscription_membership + plan_offering
claim_financial	claim_line + claim_adjustment + payment_remittance
claim_enriched	claim_header + claim_line + member_eligibility + practitioner_role + supplier_location + network_participation + contracts/rates
eligibility_change_audit	coverage + enrollment history changes
dq_exception	Validation failures across source and Silver processing
change_impact	CDC changes affecting downstream Silver/Gold calculations

Example of our Silver architecture

My architectural recommendation: Keep this two-level Silver design. It is valuable for learning because you will first master basic source-to-Silver processing and then independently develop complex joins, temporal relationships, financial calculations, and incremental recalculations.

This is the structure we'll follow when I give you individual Silver mapping specifications.
